With You

NTN-SNR THE STRENGTH OF A GROUP

NTN Corporation, a global leader in bearings, specializes in designing, developing and producing spherical roller bearings.

With NTN-SNR BEARINGS, benefit from this know-how near you with:

- An extensive range of spherical roller bearings
- The constant pursuit for excellence, culminating in high levels of performance and exceptional quality
- Extended service life and unfailing reliability, as recognised by thousands of users around the world

Globally, NTN Corporation is an expert in product life cycle management, and is typified by the accessibility and commitment of its teams.

[NTN-SNR ACCOMPANIES YOU ON THE ROAD TO RELIABILITY AND PERFORMANCE](#)

CHARACTERISTICS OF THE RANGE

PRINCIPLE OF SPHERICAL ROLLER BEARINGS

Spherical roller bearings are engineered to offer excellent resistance to high temperatures and loads, meaning that they are capable of withstanding the harshest applications. They are a popular choice for absorbing misalignments, impacts and vibrations, as well as operating in polluted environments.

Misalignment

The design of the spherical roller bearings allows for misalignment between the outer ring and the inner ring with no loss of bearing performance.

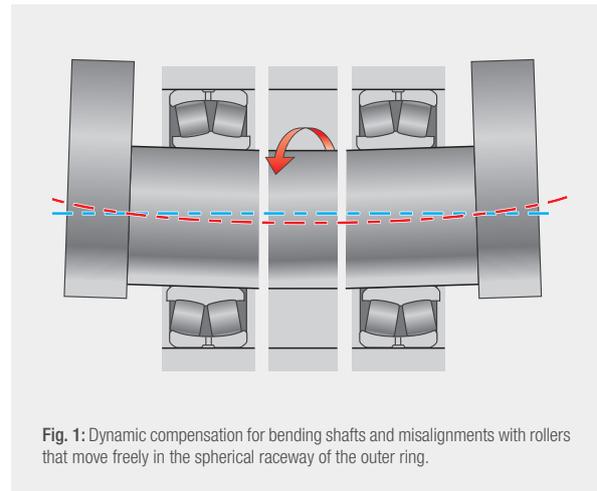

Under normal operating conditions, i.e. where the C/P ratio (dynamic bearing load vs. actual load applied) is greater than 10, the permissible angle of tilt is 0.5°.

This angle of tilt is permissible in cases where the misalignment of the inner ring is constant with respect to the outer ring and in the case of a rotating inner ring.

This value depends on the parts surrounding the bearing or on the type of external seal used. In the case of a rotating outer ring or variable misalignment, the permissible angle of tilt is reduced.

In the case of low loads, the angle of tilt may reach 2°.

For these particular cases, please contact your NTN-SNR representative.

ULTAGE QUALITY

Maintenance operations due to a fault in a component as simple as a bearing can run into hundreds of thousands of euros depending on the application (unavailability of the user's production tools, repair times and employee downtime due to the repairs).

To raise the reliability bar on your equipment, the NTN Group has developed the ULTAGE quality hallmark for its spherical roller bearings. It combines the use of superior quality materials with an enhanced design and precision manufacturing process.

ULTAGE™

ULTAGE, the generation of NTN high-performance bearings delivering:

- Unrivalled service life
- Higher speed limits
- Maximised load capacities

i Bearings designed according to **ULTAGE** rules can be identified with the **suffix E**.

ULTAGE FEATURES

- Superior grade steel
- Improved roller size
- Enhanced surface finishes
- Cage made from high-performance solid brass or drawn steel without a central guide ring
- Specific heat treatment processes

BENEFITS

- Service life doubled with increased load capacities
- Greater rigidity and stability
- Reduced in-service temperatures with improved lubricant circulation within the bearing
- Dimensional stability up to 200°C without impairing the bearing's mechanical properties
- Speed limits 20% higher than conventional designs due to the excellent surface properties

"ULTAGE: less downtime, more profit"

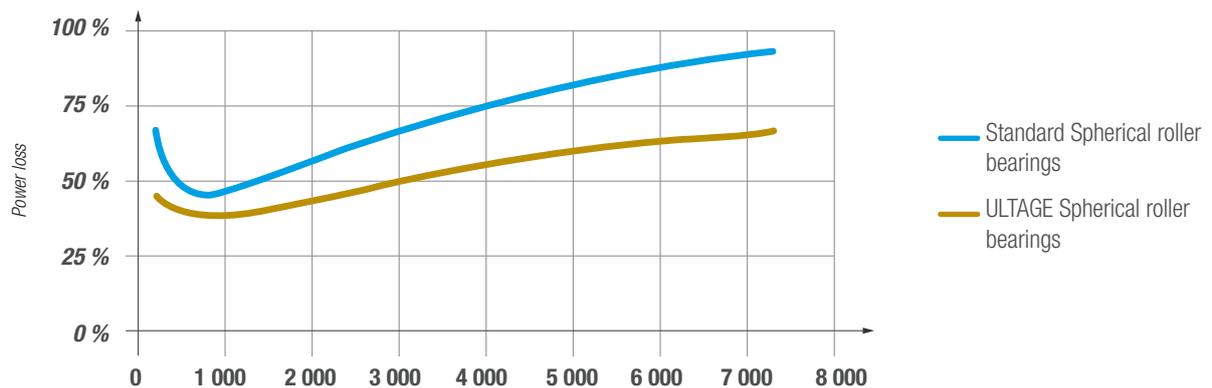

Fig. 2: Reduced power dissipation vs speed.

CONTROLLED MANUFACTURING

AN ALL-INTERNAL IRONCLAD PROCESS

Our entire range of spherical roller bearings is developed and manufactured internally in our Japanese and Italian factories.

The NTN Group is strongly committed to keeping its production processes in-house as a sign of its superlative quality and expertise, especially since its bearings are widely used in critical and costly applications. This strategy ensures that the Group exercises complete control over its range of spherical roller bearings, from product design through to marketing.

The NTN Group has spearheaded a high-performance quality assurance system for its production processes, supported by self-inspections and continuous oversight. This system assures the highest product quality over time by controlling every component of the process (means, methods, manpower, environment and materials).

Thanks to the continuous improvement approach applied to its production facilities, and its quality assurance system, the NTN Group is able to guarantee bearings with ever more precise surfaces for enhanced performance, reduced friction during operation and, consequently, improved lubrication efficiency.

For several years, NTN-SNR has integrated an environmental approach into its manufacturing processes. Accordingly, numerous initiatives have been undertaken on our production sites:

- Controlled use of the water used for cooling the production units
- Recycling of cutting oils
- Continuous monitoring of CO₂ emissions from the boilers in the thermal power plants

QUALITY: A SHARED VISION

NTN-SNR is committed to the quality of its products. All our bearings comply strictly with the most rigorous of technical requirements. The quality process is closely controlled at each stage:

- Quality of design
- Quality of product development
- Quality of production
- Quality of marketing
- Quality of services

So that you can be sure of the authenticity of our products, we have developed a label featuring a hologram that is easily identifiable and difficult to fake.

"A fully guaranteed NTN-SNR product meeting the Group's quality requirements"

SPHERICAL ROLLER BEARING

An unrivalled extensive product range!

NTN **SNR**

With You

SECTORS OF ACTIVITY AND APPLICATIONS

NTN-SNR possesses one of the widest ranges of spherical roller bearings offering high-end load capacity and speed performance. Expertise in product design and complete control over the production process guarantee the best results for the most demanding applications.

DESIGNATIONS

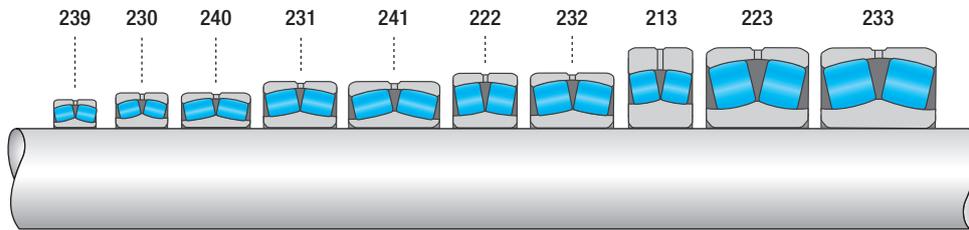

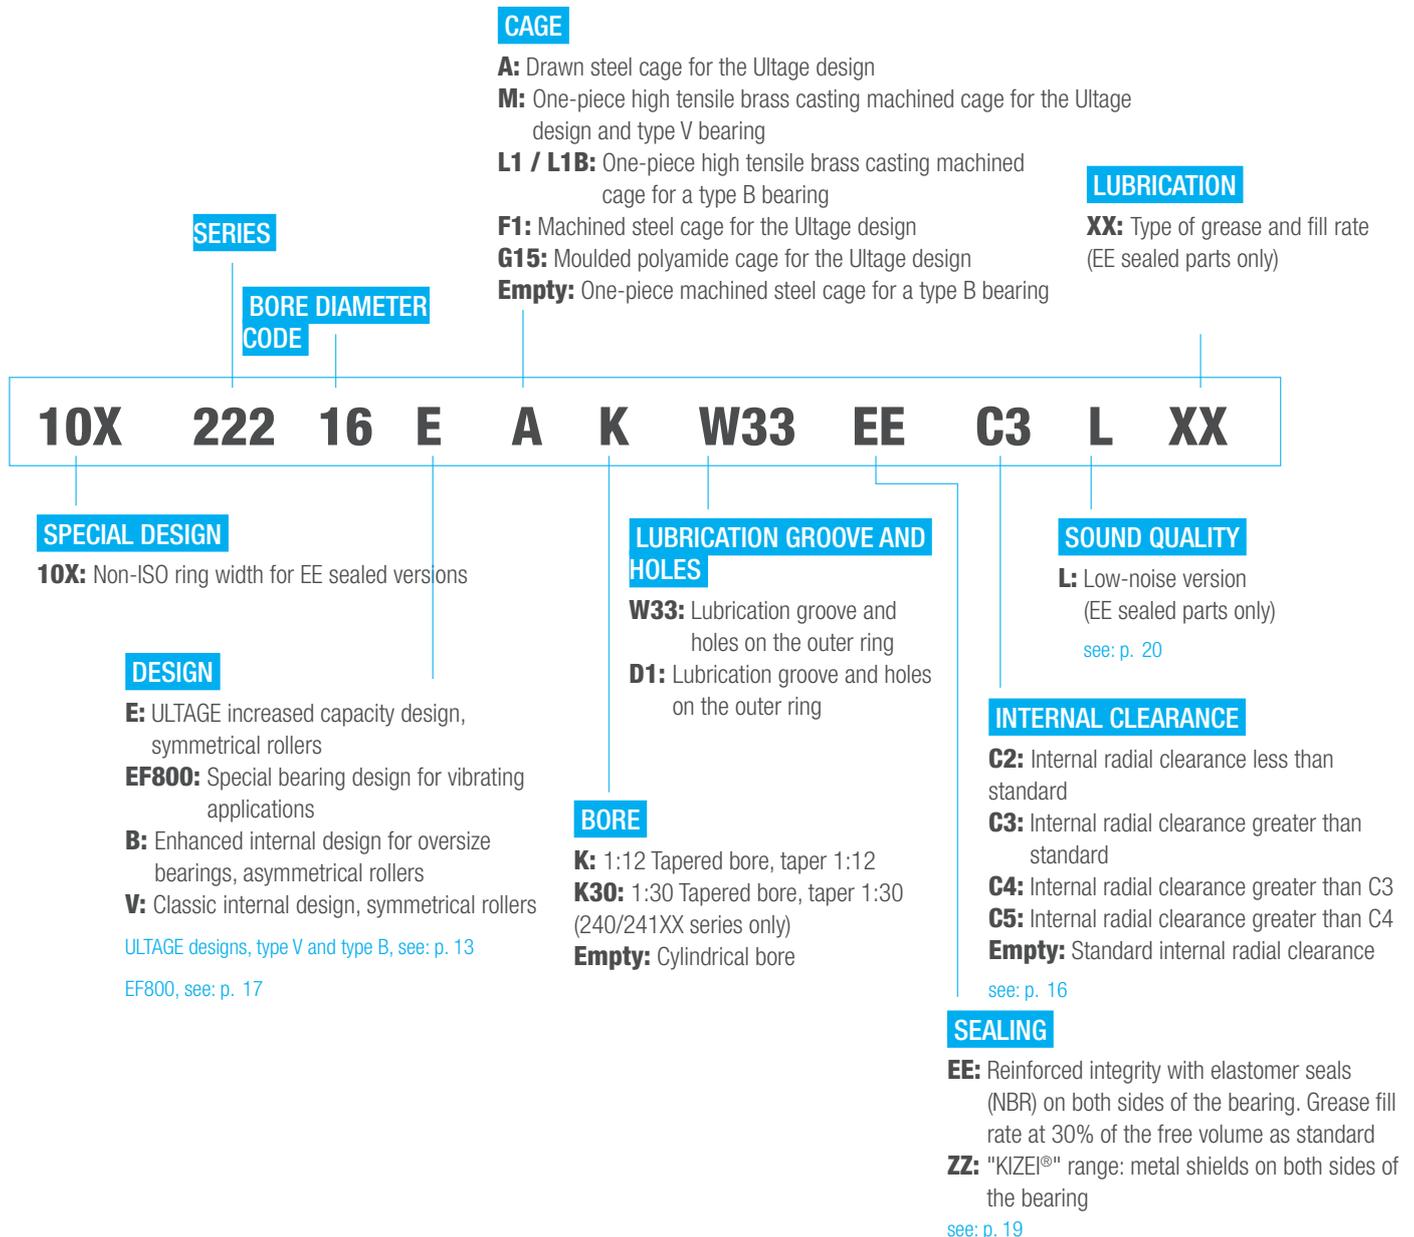

Fig. 3: Series of spherical roller bearings available from NTN-SNR

NTN-SNR proposes a full range of spherical roller bearings with cylindrical and tapered bores from 25 to 1400 mm. These bearings are available in several series designed to cater to the broadest spectrum of usages depending on your requirements in terms of loads, speeds and dimensions.

Most spherical roller bearings are proposed with the Ultage design (type E). Some products are available with a conventional design (type V) or asymmetric design specific to oversize versions (type B).

CODE SYSTEM

TYPES OF DESIGN

ULTAGE DESIGN: TYPE E

- Symmetrical rollers
- No central rib for optimal load capacity and optimum lubricant flow in the bearing
- Stabilisation of the steel for use at temperatures of up to +200°C
- Optimised internal geometry to minimise friction and heat build-up
- Cage made from drawn steel (EA), fibre glass reinforced polyamide (EG15) or machined solid brass (EM) for the harshest applications
- Lubrication groove and holes on the outer ring (W33 or D1)

Do not use a product with a fibre glass reinforced polyamide cage over 150°C

AN IMPROVED DESIGN FOR BETTER LUBRICATION

55% of bearing faults are due to lubrication defects, meaning that lubrication plays a major role in ensuring peak performance.

Just like the design, geometry and surface finish of the different bearing components, the viscosity of the lubricant is vitally important for increasing the bearing's operation and service life. The Ultage design represents the enhanced combination of all these factors.

- **No central shoulder section:** the available volume is higher so that the lubricant can flow more freely, meaning that the different parts of the bearing are constantly lubricated. This design drastically reduces the risk of overheating.
- **Wider lubrication holes and grooves:** this design feature simplifies bearing maintenance and relubrication. The number of lubrication holes on the outer ring may be 3, 4 or 8 depending on the bearing brand and size (information specified in the product tables on page 54).
- **Improved cage materials and design:** the cage is a risk-prone part of the bearing and is often the cause of faults. Special attention has been taken over the cage design (see p.14).

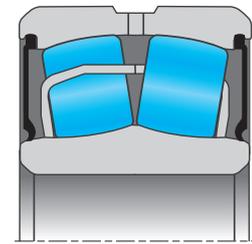

Fig. 4: Cross-sectional diagram of the Ultage design with a drawn steel cage (EA)

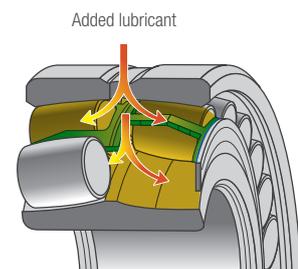

Fig. 5: The lubricant flows more freely inside the bearing

Number of lubrication holes

Outer diameter of the bearing Ø D mm		Number of lubrication holes		
		D1	W33	B
≥	≤	k	k	k
-	320	4	3-4*	
320	420	8	3-8*	
420	1000	8	8	8
1000	-	12		12

Note: For the width of the fill groove "**b**" and the diameter of the fill hole "**k**", refer to the table entitled "**spherical roller bearing references**" on pages 56 to 73 of the catalogue.

*3 or 4 / 3 or 8 lubrication holes depending on the model

Specific ULTAGE design for oversize bearings

For bearings with a bore diameter of 420 mm and above, a guide ring is added between the cage and the inner ring of the bearing. This specific design guarantees improved long-term strength for oversize bearings.

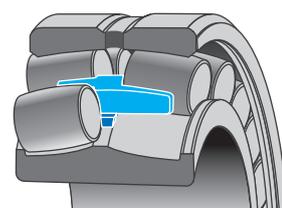

Fig. 6: Ultage design for oversize bearings

TYPE B DESIGN

- Design used for oversize bearings
- Asymmetrical rollers
- Shoulder section fixed to the centre of the inner ring
- Stabilisation of the steel for use at temperatures of up to +200°C
- Machined steel or brass cage
- Lubrication groove and holes on the outer ring (not indicated by a suffix)

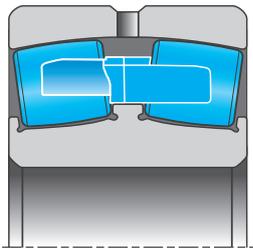

Fig. 7: Cross-sectional diagram of a type B bearing

TYPE V DESIGN

- Earlier generation to the Ultage design, type E
- Symmetrical rollers
- No central rib for optimal load capacity and optimum lubricant flow in the bearing
- Stabilisation of the steel for use at temperatures of up to +200°C
- Cage made from drawn steel or solid brass (M)
- Lateral retaining shoulder sections for the rollers
- No lubrication grooves or holes on the outer ring as standard

CAGES

ULTAGE EA DESIGN - DRAWN STEEL CAGE

"Minimal friction and heat build-up, increased service life and reduced maintenance costs"

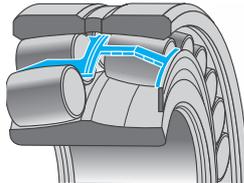

Fig. 8: Ultage design bearing with EA cage

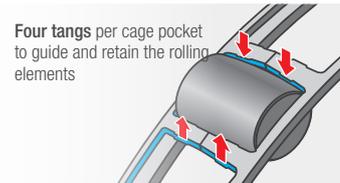

Fig. 9: Unique guidance system for perfect control

- Two steel plate window cages centred on the ground surface of the inner ring
- Precise guidance of the rollers with a unique four-tang system for perfect control of the position of the rolling elements

The steel plate cages are reinforced with a specific surface treatment process, which may either be nitriding or phosphating depending on the bearing dimensions.

Combination layer
~ 10 μm / ~ 400 HV

Diffusion layer
~ 100 μm / ~ 250 HV

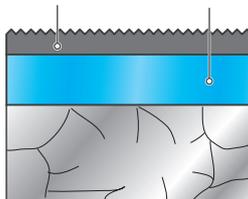

Fig. 10: Cross-sectional view of the nitriding surface treatment for a steel plate cage

CAGES WITH NITRIDING SURFACE TREATMENT

- Increased surface hardness of the cage for superior wear resistance
- Maintained resistance in the cage core to improve impact resistance
- Lower friction coefficient for greater in-service performance at high speeds
- Good corrosion resistance

Phosphate layer
~ 20 μm

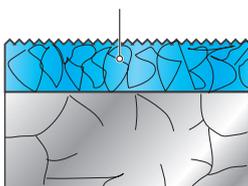

Fig. 11: Cross-sectional view of the phosphating surface treatment for a steel plate cage

CAGES WITH PHOSPHATING SURFACE TREATMENT

- Lower friction coefficient for greater in-service performance at high speeds
- Good corrosion resistance

ULTAGE DESIGN EM - HIGH TENSILE BRASS CASTING MACHINED CAGE

"Especially suited to the most demanding applications"

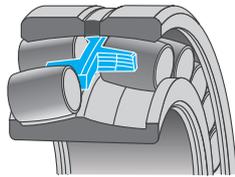

Fig. 12: Ultage design bearing with EM cage

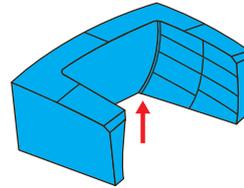

Fig. 13: Contoured pocket to guide the rolling elements

- Machined brass alloy one-piece cage centred on the rolling elements
- Simple design without a guide ring or fixed central shoulder section to avoid a cage/ring seizure in the event of thermal expansion
- Contoured profile of the cage pockets to guarantee perfect stability of the rolling elements under the harshest operating conditions
- Self-lubricating properties of the brass to reduce overheating at high speed

ULTAGE DESIGN EG15 – MOULDED POLYAMIDE CAGE (on request; contact us)

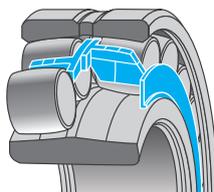

Fig. 14: Ultage design bearing with EG15 cage

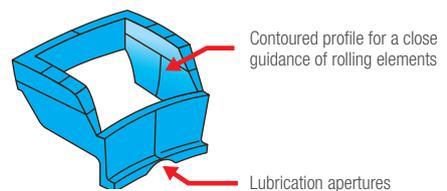

Fig. 15: Perfect guidance of the rollers with a soft material offering a low friction coefficient

Unsuitable for applications over 150°C

- 6.6 moulded polyamide cage reinforced with 25% glass fibre
- Perfect guidance of the rollers with a soft and elastic material offering a low friction coefficient
- Enhanced cage design to ensure perfect distribution of the lubricant

INTERNAL RADIAL CLEARANCE AND TOLERANCES

NTN-SNR bearings are delivered with normal precision according to ISO 492.

The internal radial clearance is defined by ISO 5753.

DEDICATED PRODUCTS

EF800 SERIES FOR HIGH-VIBRATION APPLICATIONS

For high-vibration applications (screens, crushers and grinders), the generally recommended internal clearance is C4. In order to avoid any risk of preload on the bearings, linked to adjustment defects or deformation of the shaft or housing seating surfaces, NTN-SNR proposes a special radial clearance range in the C4 group, reduced to 2/3 of the tolerance. This new range facilitates the achievement and control of the final radial clearance after assembly and takes account of the specific operating conditions for these vibrating materials.

ULTAGE™

Products corresponding to the specification can be identified by the suffix **EF800**.

CHARACTERISTICS

- ULTAGE bearing with symmetrical rollers and machined brass alloy one-piece cage centred on the rolling elements
- Available in a range of bore diameters from 40 to 200 mm
- Cylindrical and tapered bores available
- No floating guide ring or fixed central shoulder section to avoid any risk of a cage/ring seizure in the event of thermal expansion
- Special tolerances for the outer diameter and bore
- Outer diameter: the tolerances of the EF800 specification guarantee the fixed adjusting of the outer ring in its housing for a type P6 fit
- Cylindrical bore: the reduced tolerances defined by the EF800 specification guarantee a sliding adjusting of the inner ring over the shaft produced with a type g6 or f6 tolerance
- Tapered bore: the reduced tolerances enabling limitation of the axial displacement of the inner ring when setting the clearance during assembly, thereby facilitating the assembly operations

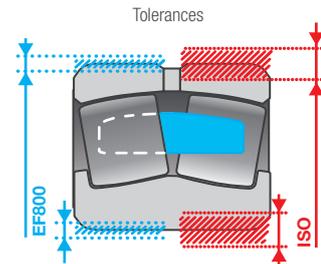

Fig. 16: Special tolerances for the outer diameter and bore

BENEFITS

- Increased service life
- Wider maintenance intervals
- Greater operational profitability

Note: In certain cases, applications may necessitate the use of a clearance other than group C4. Upon request, we can deliver bearings in groups C3, EF801 series or CN, EF802 series. For the EF801 and EF802 series, just like the EF800 series, the clearance range is reduced to 2/3 of the tolerance.

SEALED BEARINGS WITH ELASTOMER SEALS

To prevent ingress and contamination if bearings are used in hostile environments, such as outdoors or in dusty conditions, you are advised to use sealed bearings.

These compact solutions offer a constant hermetic seal even when there is bending of the shaft (up to 0.5° maximum).

CHARACTERISTICS

- Identical internal design to the open bearings with the ULTAGE EA design
- Non-ISO width with a minimal increase in order to integrate seals (10X prefix)
- Specially designed NBR seal to guarantee impermeability by means of constant contact pressure of the lip, even in the event of misalignment
- Pre-filled bearing with a quantity and quality of lubricant suited to high loads; no relubrication is required for applications below 70°C
- Operation up to +120°C; for higher temperatures, the materials of the seals and the quality of the lubricant need to be adapted accordingly

"Our seals with their superior geometric design are tested in our laboratories under the most extreme conditions to guarantee their reliability and their performance for your applications"

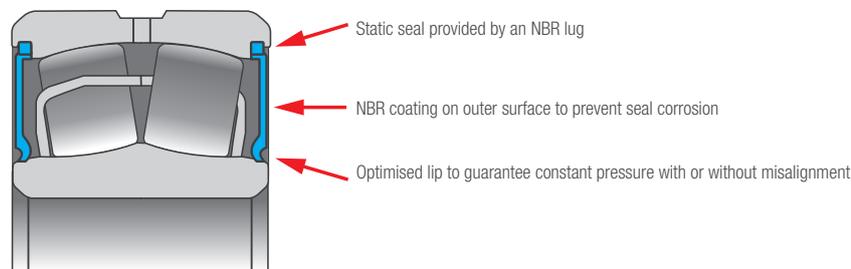

Fig. 17: Ultage design sealed bearing

BENEFITS

- Increased service life
- Wider maintenance intervals
- Greater operational profitability
- Protection of the environment

EE sealed spherical roller bearings are frequently used in such applications as steel industry conveyors, mines, power transmission systems for elevators and printing machinery.

Note: During mounting, feeler gauges cannot be used to check the internal clearance of sealed bearings due to the seals. All the specific mounting recommendations and advice for checking the clearance for this type of bearing are explained on pages 45-46.

SPECIAL CASE OF LOW-NOISE APPLICATIONS

Some applications, such as the power transmission system for elevators, are particularly demanding in terms of the noise made by the bearings. Therefore, NTN-SNR offers sealed spherical roller bearings with low vibration levels, which are identified by the suffix L and which are available on request. Their improved geometric and functional characteristics significantly reduce the amount of noise generated.

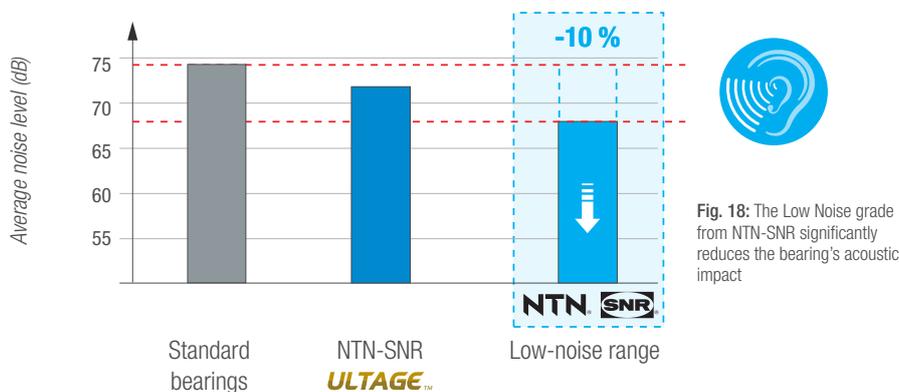

Fig. 18: The Low Noise grade from NTN-SNR significantly reduces the bearing's acoustic impact

ALL-IN-ONE BEARING KITS: AN INNOVATIVE SOLUTION TO ASSIST YOU

To bring greater simplicity to your partial and full maintenance operations, NTN-SNR offers a wide array of ready-to-use kits containing spherical roller bearings and the associated products required for their operation, all of which in a single container. Several options are available to accurately satisfy your specific needs.

CHARACTERISTICS

NTN-SNR offers three types of kit:

- **One kit for partial maintenance**, comprising an ULTAGE sealed spherical roller bearing, a special sealed mounting sleeve and two special sealed locating rings
- **One kit for full maintenance**, comprising an ULTAGE sealed spherical roller bearing, an SNC split plummer block, a special sealed mounting sleeve, two special sealed locating rings, two sets of NBR seals and a plug
- **One kit for full maintenance**, comprising an ULTAGE open spherical roller bearing, an SNC split plummer block, a mounting sleeve, two locating rings, two sets of NBR seals, a plug and a DRIVE BOOSTER automatic lubrication system
- All kits contain technical instructions with advice on how to adjust the internal clearance through axial displacement and relubrication instructions
- Kits are available for shaft diameters between 35 and 90 mm
- Each kit reference is available with a standard clearance (CN) or increased clearance (C3)

"The premium grade of our spherical roller bearing solutions with split plummer blocks can bring ultimate reliability to your facilities."

BENEFITS

- Streamlined inventory: only one reference to order and store
- Limited risk of errors and omissions: all specific components for each bearing are included in the kit
- Flexible use: each kit can be used for fixed or floating bearing units

KIZEI®: THE FIRST SPHERICAL ROLLER BEARING WITH METAL SHIELDS

NTN-SNR's R&D department has pioneered an unprecedented solution to increase the service life of your spherical roller bearings.

CHARACTERISTICS

- ULTAGE load capacities and speed
- **ISO dimensions:** 100% interchangeable with an open spherical roller bearing

Fig. 19: The KIZEI® bearing is available in ISO widths, just like an open spherical roller bearing

- Premium quality nitrided steel plate cage and shields for maximum impact strength and superior corrosion resistance
- Extensive range of operating temperatures from -40°C to +200°C
- **Kizei® is supplied ungreased:** the initial lubrication process is similar to an open spherical roller bearing; 30% of the free volume must be filled with the appropriate grease
- The bearing can be lubricated while in service via the dedicated holes and grooves on the outer ring
- **Internal inspection possible** for easier maintenance
- **Easy mounting process:** no special tools are required, and the clearance can be checked after mounting

BENEFITS

- Improved production performance with the longer service life
- Reduced maintenance costs
- Easy to use

ULTAGE™

*Valid against solid contamination - Not suitable for liquids

PRODUCTS WITH SOLID LUBRICATION

For highly specific operating constraints where traditional brands of grease quickly show their limitations (low-amplitude oscillations, high centrifugal forces, washing out, pollution, difficult access, etc.), NTN-SNR has developed a solid lubrication concept suited to spherical roller bearings.

CHARACTERISTICS

- Porous polymer matrix that fills the free volume of the bearing and can contain three to four times more oil than conventional grease for improved lubrication
- Suitable for speeds less than 100,000 N.Dm

In applications where the bearing is subject to centrifugal phenomena, a traditional lubricant can be ejected instantaneously from the bearing, whereas a solid lubricant allows the oil to be kept within the bearing and to operate for thousands of hours.

BENEFITS

- Longer service life since oil is constantly supplied to the bearing core
- No re-lubrication required
- Excellent resistance to centrifugal forces
- Environmental protection by reducing lubricant leaks
- Sealing effect: the solid lubricant acts as a shield against external particles

NTN-SNR is at your disposal to determine the suitability of this concept in your applications.

TECHNICAL INFORMATION

NOMINAL SERVICE LIFE

The nominal service life, L_{10} , recommended by ISO 281, is given by the equation $L_{10} = (C / P)^n$ where $n=10/3$ for the roller bearings. This equation is defined for a reliability level of 90% under normal operating conditions.

Nominal service life

$$L_{10} = (C/P)^n \text{ in millions of revs}$$

or

$$L_{10} = (C/P)^n \cdot 10^6 / 60N \text{ in hours}$$

C = Basic dynamic load (Newton)

P = Equivalent dynamic load (Newton)

N: Rotation speed (rpm)

Equivalent dynamic load P

$$P = F_r + Y_1 \cdot F_a \text{ where } F_a/F_r \leq e$$

$$P = 0.67F_r + Y_2 \cdot F_a \text{ where } F_a/F_r > e$$

P = Equivalent dynamic load (Newton)

F_r = dynamic radial load (Newton)

F_a = dynamic axial load (Newton)

e, Y_1 , Y_2 factors according to dimensions tables (see from page 54)

Equivalent static load P_0

$$P_0 = F_{0r} + Y_0 \cdot F_{0a}$$

P_0 = Equivalent static load (Newton)

F_{0r} = Static radial load (Newton)

F_{0a} = Static axial load (Newton)

Y_0 = Factor according to dimensions table

Safety factor

$$f_s = C_0 / P_0$$

C_0 basic static capacity defined in the dimensions tables (Newton)
(see from page 54)

Minimum basic values for the static safety coefficient f_s :

- 1.5 to 3 for severe conditions
- 1 to 1.5 for normal conditions
- 0.5 to 1 for operations with no particular noise or precision requirements

If you are looking for a bearing operating under harsh conditions, the safety coefficient f_s must be high.

Minimum radial load

In order to avoid slippage phenomena between the rolling elements and the raceways, particularly in the case of high speeds or accelerations, a minimum load must be applied to spherical roller bearings.

$$P_{rm} = 0.01C_0$$

P_{rm} = minimum radial load (Newton)

C_0 = basic static load (Newton)

Maximum axial load

Spherical roller bearings can support high axial loads.

Generally, $F_a/F_r \leq e$ can be used, however it is recommended that you do not exceed the following value $F_a/F_r = 0.3$.

In the event of high loads combined with high speeds, the rise in the bearing temperature must be taken into account.

ADJUSTED NOMINAL SERVICE LIFE

BASIC NOMINAL SERVICE LIFE

- **The basic nominal service life L₁₀** is often a satisfactory estimation of the bearing performance levels. This service life is understood to accommodate 90% reliability and conventional operating conditions. It may be necessary in certain applications to calculate the service life for a different level of reliability or for specific lubrication and contamination conditions.

With steels for high-quality bearings, it is possible, for low loads and under favourable operating conditions, to obtain extremely long service lives compared to L₁₀. A shorter service life than L₁₀ may apply under unfavourable operating conditions.

Below a certain load C_u (defined in the ISO 281 standard as "the fatigue load limit"), a modern high-quality bearing can achieve a practically infinite service life if the lubrication conditions, cleanliness and other operating conditions are favourable.

This load C_u can be determined precisely according to:

- The types of bearing
- Their internal geometry
- The fatigue limit of the raceway material

ADJUSTED NOMINAL SERVICE LIFE

The ISO 281 standard provides the necessary formula for obtaining a sufficient approximation based on the static capacity of the bearing.

- **The ISO 281** international standard introduces a correction factor of duration a_{ISO} which enables an adjusted nominal service life to be calculated according to the formula:

$$L_{nm} = a_1 a_{ISO} L_{10}$$

The coefficient a₁ is designed to calculate the duration for a reliability level different to 90% of the original formula.

The coefficient a_{ISO} is used to estimate the influence of the lubricant and of the contamination on the bearing service life. It takes account of the fatigue limit of the bearing steel.

Since the evaluation method for a_{ISO} defined by ISO 281 is fairly difficult to apply by a non-specialist user, NTN-SNR has looked for the best way to supply its customers with an easy way of determining a_{ISO} based on the hypotheses of the standard.

- > that the fatigue load C_u depends directly on the static capacity of the bearing
- > that the contamination factor is constant whatever the lubrication conditions and the average diameter of the bearing.

The method proposed by NTN-SNR enables rapid, graphic evaluation of the coefficient a_{ISO}. Our engineers are at your disposal to determine this coefficient more precisely if required.

METHOD FOR DETERMINING a_{ISO} (ISO 281)

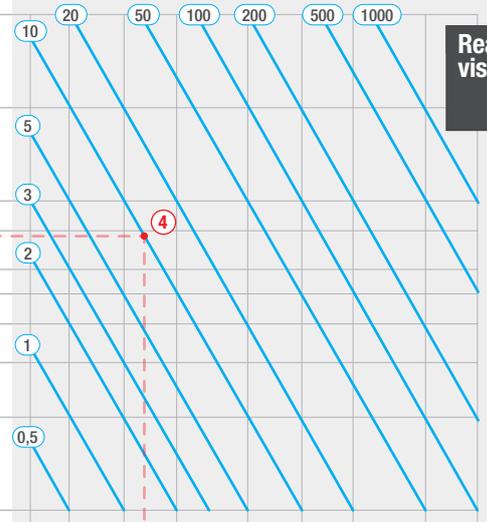

The following diagram can be used to determine a_{ISO} for double-row spherical roller bearings according to the following method:

1. Define the viscosity of the lubricant at the operating temperature based on the diagram on page 30.
Determine the viscosity of the base oil for greased bearings.
2. Define the pollution level:
 - **High cleanliness**
Oil filtered through an extremely fine filter; usual conditions for bearings that are greased for life and sealed.
 - **Normal cleanliness**
Oil filtered through a fine filter; usual conditions for bearings that are greased for life and equipped with a shield.
 - **Slight contamination**
Slight contamination in the lubricant
 - **Typical contamination**
Oil with coarse filtration; presence of wear and tear particles or particles from the surrounding environment.
Usual conditions for lubricated bearings with no integrated seal.
 - **For major contamination**, consider that a_{ISO} will be less than 0.1
3. Based on the loads applied to the bearing, calculate the equivalent load P and the static capacity / equivalent load ratio: C_0 / P .
4. In graph 1 on page 29, determine point 1 according to the pollution level and the value C_0 / P .
5. Determine point 2 based on the average diameter of the bearing: $D_m = (\text{bore} + \text{outer diameter}) / 2$
6. Determine point 3 according to the rotational speed of the bearing.
7. Determine point 4 according to the viscosity of the lubricant at the operating temperature.
8. Point 5 at the intersection between the straight lines deriving from points 2 and 4 defines the value zone for a_{ISO} .

- Point 1: functioning with typical pollution, with a charge level $C_0/P = 22$
- Point 2: with an average diameter D_m of 40 mm
- Point 3: rotation speed of 3,000 rpm
- Point 4: and with a lubricant of viscosity 10 cSt
- Point 5: the coefficient a_{iso} is: 1

DETERMINING THE MINIMUM VISCOSITY REQUIRED FOR THE OPERATING TEMPERATURE

VISCOSITY-TEMPERATURE DIAGRAM

The oils used for lubricating bearings are generally mineral oils with a viscosity in the vicinity of 90. The suppliers of these oils state the precise characteristics of their products and, in particular, the viscosity-temperature diagram. Failing this, the following general diagram will be used.

Since the oil is defined by its nominal viscosity (in centistokes) at the nominal temperature of 40°C, the viscosity at the operating temperature may be deduced.

SPEEDS

THERMAL REFERENCE SPEED N_{OR}

The thermal reference speed is the rotational speed of the inner ring at which a thermal equilibrium is attained between the heat produced by the friction in the bearing and the heat flow emitted via the contact surface (shaft and housing) of the bearing under reference conditions.

The reference speed values indicated in the tables are in compliance with standard ISO 15312. The reference conditions for this standard have been chosen to apply both for oil lubrication and for grease lubrication. This standard applies to bearings up to and including a bore diameter of 1000 mm.

Thermal reference speed n_{Or} : speed at which the bearing temperature reaches +70°C under the reference conditions.

REFERENCE CONDITIONS DETERMINING THE FORMATION OF HEAT THROUGH FRICTION:

- Reference temperature of the bearing on the stationary outer ring Θ_r : 70°C
- Reference ambient temperature of the bearing Θ_{Ar} : 20°C
- Reference load $P_{1r} = 0.05 \times C_{Or}$ (5% of the basic static radial load, as pure radial load)
- Lubricant: high-pressure, additive-free mineral oil with, at $\Theta_r = 70^\circ\text{C}$, a kinematic viscosity of $\nu_r = 12\text{mm}^2/\text{s}$ (ISO VG32).

MATHEMATICAL CALCULATION ACCORDING TO STANDARD ISO 15312

$$\frac{\pi \cdot n_{\theta r}}{30 \cdot 10^3} \cdot [10^{-7} \cdot f_{\theta r} \cdot (v_r \cdot n_{\theta r})^{2/3} \cdot d_m^3 + f_{1r} \cdot P_{1r} \cdot d_m] = q_r \cdot A_r$$

$n_{\theta r}$: Thermal reference speed

$f_{\theta r}$: Adjustment factor for the moment of friction independent of the load (the values as per ISO 15312 are for information purposes only)

f_{1r} : Adjustment factor for the moment of friction depending on the load (the values as per ISO 15312 are for information purposes only)

v_r : Kinematic viscosity of the lubricant

d_m : Average diameter of the bearing $D_m = 0.5(D+d)$

q_r : Reference thermal flow density $q_r = 0.016 \text{ W/mm}^2$. If $A_r > 50000 \text{ mm}^2$ then $q_r = 0.016(A_r/50000)^{-0.34}$

A_r : Reference thermogenic surface area $A_r = \pi \times B(D+d)$

LIMITING SPEED

The limiting speed is the maximum permissible speed which depends on the mechanical limits, such as the tensile strength of the constituent parts of the bearing.

The limiting rotational speed is based on practical experiments. It takes account of additional criteria such as silent operation, the seal functions, the stability or resistance of the cage, the lubrication of the cage guide surfaces, the centrifugal and gyrating forces that act on the rolling elements and other speed limitation factors.

THERMALLY SAFE OPERATING SPEED

The admissible rotational speed n_{adm} is the rotational speed at which the average temperature of the bearing reaches the permissible limiting value under actual operating conditions. To determine the thermally safe operating speed of the bearing in its application, it is necessary to take account of the influence of the load and of the kinematic viscosity on the reference speed. When the load and viscosity parameters are in excess of the reference values, the friction resistance will increase and the temperature of the bearing will be higher. In this case, the bearing cannot operate at the thermally safe reference speed unless higher temperatures are permitted by the bearing and its application.

The influence of the load and of the kinematic viscosity of the lubricant may be determined on the basis of diagrams 1 and 2, page 36.

To determine the permissible speed of your bearing (see from page 54)

OIL LUBRICATION

- f_p : for the influence of the equivalent dynamic load P
- f_v : for the influence of the viscosity

If the reference temperature needs to remain constant at 70°C, the thermally safe operating speed is determined based on:

$$n_{adm} = n_{\theta r} \cdot f_p \cdot f_v$$

n_{adm} = thermally safe operating speed of the bearing, rpm

$n_{\theta r}$ = thermal reference speed

f_p = adjustment factor for the equivalent dynamic load P

f_v = adjustment factor for the oil viscosity

GREASE LUBRICATION

The diagram for determining factor f_v is also suitable for grease lubrication. In this case, the standard stipulates a kinematic viscosity of the base oil of between ISO VG 100 and ISO VG200 at +40°C with a quantity of grease equal to 30% of the free volume in the bearing.

To determine factor f_v in the case of grease lubrication, select the value of f_v from diagram 1 for the viscosity of the base oil at +40°C for the chosen grease and divide by f_v for the viscosity of the base oil ISO VG 150 (average value of the base oils permitted by the standard)

$$n_{adm} = n_{thr} \cdot f_p \cdot \frac{f_v \text{ real viscosity of the base oil}}{f_v \text{ viscosity of the base oil ISO VG 150}}$$

Example

An NTN-SNR ULTAGE 22216EA spherical roller bearing with a factor of $P/C_0=0.2$ lubricated with an oil of oil viscosity of ISO VG 220 mm^2/s at 40°C.

$$d_m = 0.5(80+140) = 110\text{mm}$$

$$n_{thr} = 4200 \text{ rpm}$$

$$\text{In diagram 1: } f_v = 0.83$$

$$\text{In diagram 2: } f_p = 0.5$$

The thermally safe operating speed in these conditions is:

$$N_{adm} = 4200 \times 0.83 \times 0.5 = 1740 \text{ rpm}$$

Diagram 1: correction factor f_v

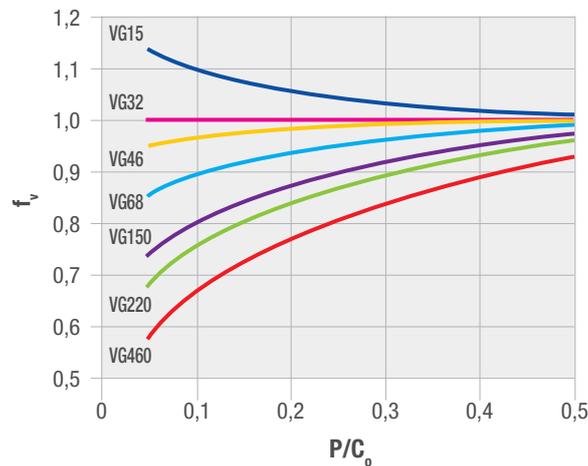

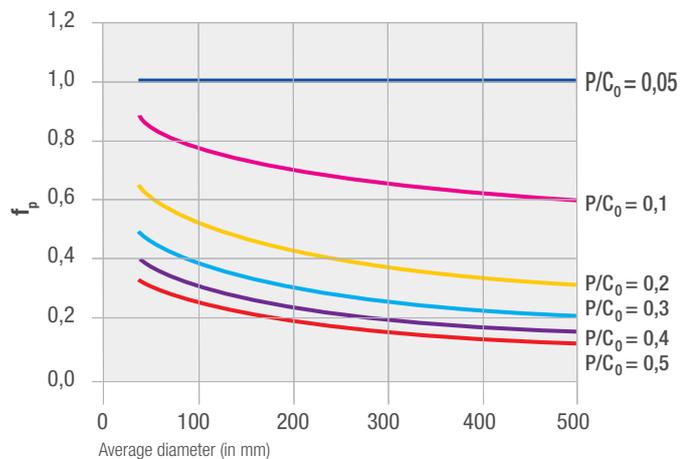

Diagram 2: correction factor f_p

In the case of operation at speeds approaching the limits stated in the bearing tables, please contact your NTN-SNR representative.

LUBRICATION

Only correct lubrication will guarantee optimal operation of the bearing and of the associated mechanical unit.

Our field experience shows that:

- 55% of premature faults with bearings result from inappropriate lubrication
- imperfect lubrication significantly reduces the service life of the bearing

Lubrication operations are often neglected on account of the difficulty of accessing the bearings and inadequate knowledge of the properties of many lubricants on the part of the user.

Since the choice of lubricant, the method of lubrication, the precise quantity to inject into the bearing and the monitoring frequency need to be studied carefully, our teams are on hand to advise you.

PRINCIPLE AND BENEFITS OF GOOD LUBRICATION

- By interposing a film of lubricant (oil film) between the rolling elements and the raceway, lubrication prevents wear and tear and seizure of the elements through metal-to-metal contact.
- It also protects the parts from corrosion.
- It provides a seal against liquids and external pollution and eliminates the impurities created by the movement of the parts.
- It reduces friction, and therefore limits the power consumed by the machine, thereby reducing energy costs.
- In the case of oil circulation, it evacuates the heat build-up and thus contributes to the thermal equilibrium of the machine.

The service life of the bearing is directly linked to the efficiency of the oil film, which depends:

- On the characteristics of the lubricant and therefore on its capability to resist high temperatures and vibrations, etc.
- On the load conditions and the bearing rotation speed

General-purpose greases do not always correspond to the specific requirements of certain applications. Since the bearings have to operate under conditions of high load, speed or temperature, or in the presence of water, humidity or vibrations, they require the use of carefully-selected lubricants.

NTN-SNR has consistently been involved in research in this field with the world's top lubricant manufacturers. In this way we have built up knowledge and practical experience of most of the lubricants applicable to bearings.

CHOICE OF LUBRICANT TYPE

	OIL LUBRICATION	GREASE LUBRICATION
BENEFITS	<ul style="list-style-type: none"> • Good bearing penetration • Good physical-chemical stability • Cooling • Easy control of the lubricant: state and levels 	<ul style="list-style-type: none"> • Cleanliness of the mechanism • Easier to ensure a good seal • Protective barrier • Easy assembly • Easy handling • Reduced or zero lubricant top-ups • Possible use of pre-lubricated bearings
DRAWBACKS	<ul style="list-style-type: none"> • Perfect seal required on assembly • In the event of prolonged stoppage, poor protection against oxidisation and humidity • Start-up delays when independent circulation prior to rotation is required 	<ul style="list-style-type: none"> • Higher friction coefficient than with oil • Inferior heat evacuation • Replacement (if needed) requires removal and cleaning of the bearing • No possibility of checking the grease level, therefore necessary to use a reliable grease or periodically top-up in order to compensate for leakage, pollution or ageing

CHARACTERISTICS OF GREASES

A grease is a semi-fluid to solid product obtained by dispersal of a thickening agent (soap) in a lubricating liquid (mineral or synthetic oil).

To provide certain specific properties, additives may be included. The growing use of bearings lubricated with grease, associated with the development of lifelong lubrication, makes the grease an integral component of the bearing. The service life of the bearing and its behaviour in various environments are largely determined by the properties of the grease used.

PHYSICAL-CHEMICAL CHARACTERISTICS

Consistency

- The NLGI (National Lubrication Grease Institute) grade corresponds to a penetration value in the grease used (according to test specification ASTM/D217).
- For bearings, the chosen consistency is in general grade 2.

NLGI GRADES	PENETRATION	Consistency
0	385 - 355	Semi-fluid
1	340 - 310	Very soft
2	295 - 265	Soft
3	250 - 220	Mean
4	205 - 175	Semi-hard

Viscosity of the base oil: generally defined in cSt (mm²/s) at 40°C

Density: in the region of 0.9

Drop point: temperature at which the first liquefied drop falls following heating of a sample

Order of magnitude: 180°C/260°C depending on the constituent components of the grease. The maximum temperature of use of the grease is always far below the drop point.

FUNCTIONAL SPECIFICATIONS

The working conditions to which the lubricant is subjected (rolling, blending) require special bearing greases that cannot be selected exclusively on the basis of their physical-chemical characteristics.

The NTN-SNR Research & Testing centre is constantly carrying out approval tests on bearings to allow us to provide advice about the grease best suited to a given application.

The approval specifications relate to the following basic criteria:

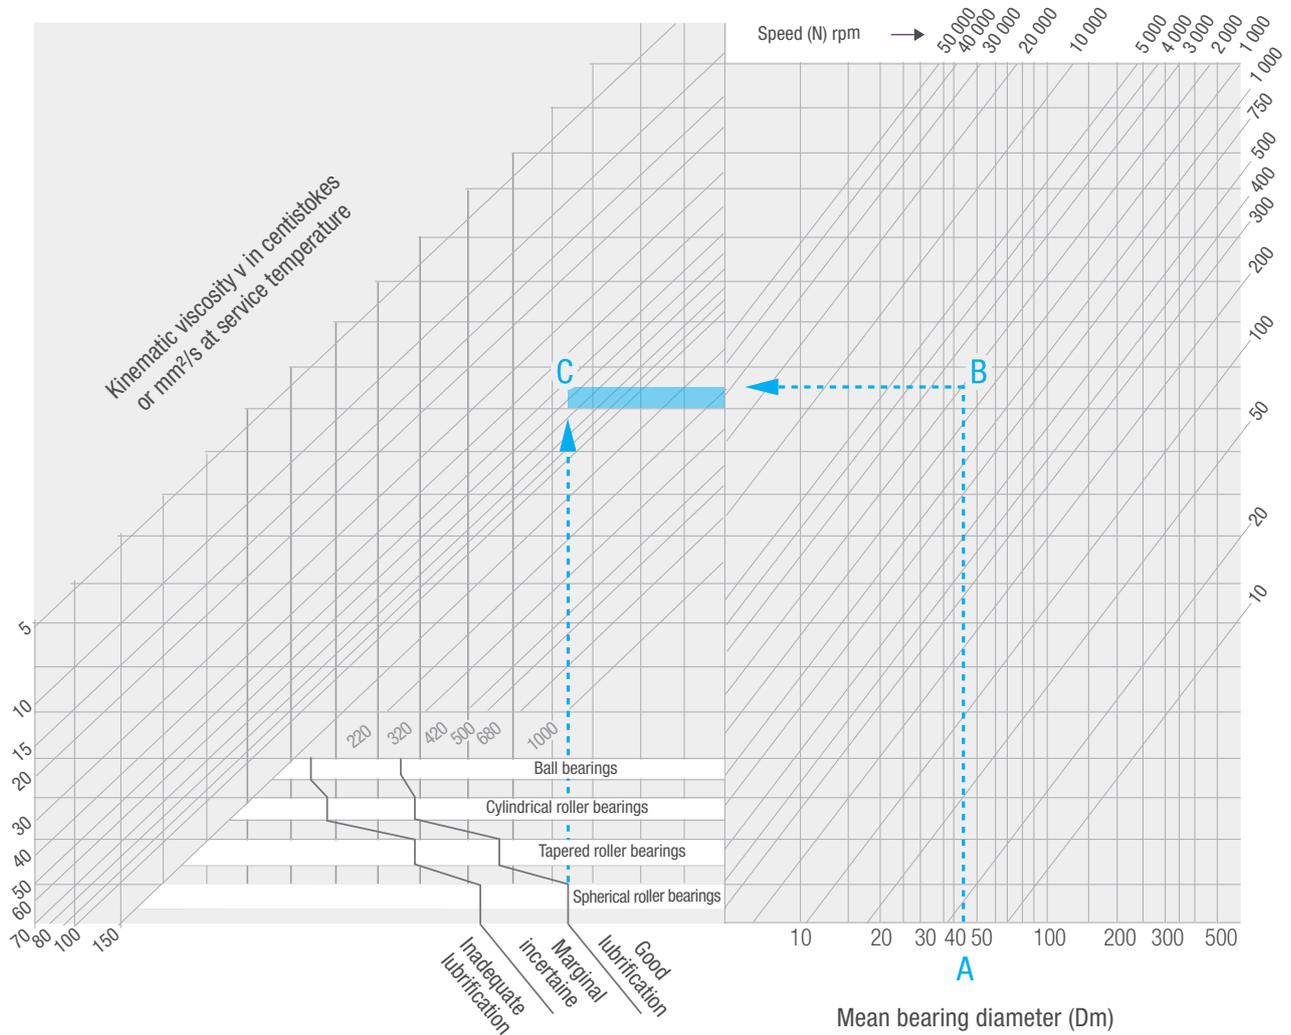

- Endurance of ball bearings
- Endurance of roller bearings
- Water resistance
- Resistance at high and low temperatures
- Adherence (centrifugation)
- Resistance to vibrations (false brinelling)
- Resistance to high speeds

These criteria may be supplemented depending on the result that the customer seeks. Grease selection for a particular application is a compromise carried out on the basis of the technical specifications of the application.

For further information about the technical characteristics of lubricants and their selection criteria, please consult our Experts & Tools catalogues or contact your NTN-SNR representative.

Tools for calculating bearing lubrication needs

CHOICE OF LUBRICANT VISCOSITY (OIL OR GREASE)

- Determine the average diameter of the bearing $A = (\text{Bore} + \text{outer diameter})/2$
- Find, by following point B on the graph, the intersection with the bearing rotation speed line
- Identify point C, intersection of the horizontal line deriving from B and the vertical line starting from the efficient lubrication limit, according to the type of bearing
- Determine the value of the oblique line passing via C (60 in the present case)
- Calculate the viscosity of the lubricant to be chosen, taking account of the operating temperature of the bearing

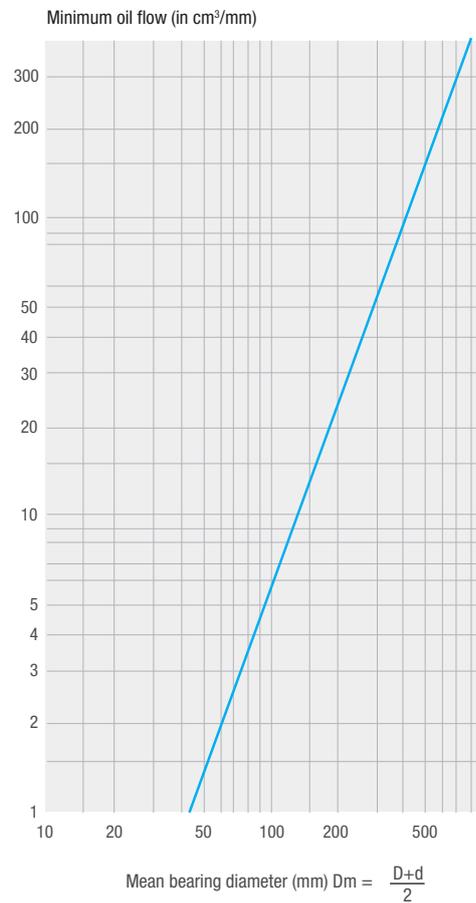

On the vertical scale (table on page 30), note the value of the calculated basic viscosity.

Identify the intersection between this value and the operating temperature of the bearing

The desired viscosity is the value of the oblique line passing via this intersection (approximately SAE 50, or VG300 in the present case)

DOSAGE OF LUBRICANTS AND RELUBRICATION

OIL LUBRICATION (MINIMUM QUANTITY)

LUBRICATION WITH GREASE (DOSAGE)

Excessive grease may cause overheating.
The grease must occupy 20 to 30% of the free volume inside the bearing.

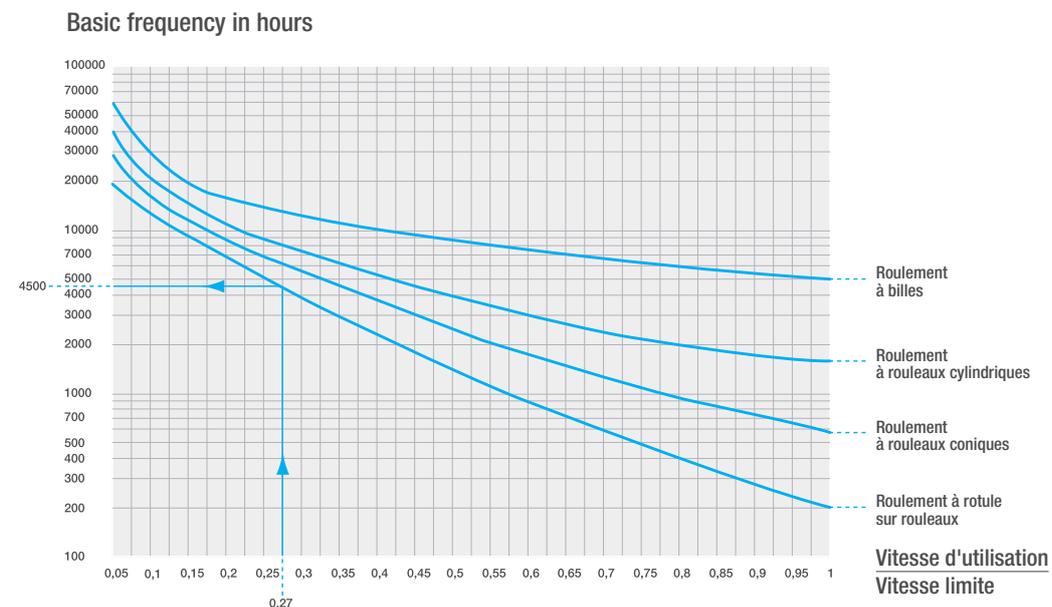

Calculation formula for the weight of grease required:
 $G = 0,005 D.B$

G = Gram (or cm³)
D = External diameter of the bearing in mm
B = Width of the bearing in mm

Exceptions:

- The quantity of grease may be increased by 20% for housings equipped with a grease evacuation orifice
- A bearing rotating at very low speed will tolerate complete filling

RELUBRICATION FREQUENCY

The basic relubrication frequency (F_b) depends on the type of bearing and the ratio of the speed of usage to the limiting speed stated in the bearing specifications.

This basic frequency needs to be adjusted by the following coefficients according to the specific environmental conditions of the mechanism (dust, humidity, impacts, vibration, vertical axis, operating temperature, etc) according to the relation: $F_c = F_b \times T_e \times T_a \times T_t$

Conditions	Environment	Applications	Temperature		
	Dust Humidity Condensation	With impacts Vibrations Vertical axis	Level	For standard grease	For high-temperature grease
Coefficients	T_e	T_a		T_t	T_t
Mean	0.7 to 0.9	0.7 to 0.9	75°C	0.7 to 0.9	-
High	0.4 to 0.7	0.4 to 0.7	75°C to 85°C	0.4 to 0.7	0.7 to 0.9
Very high	0.1 to 0.4	0.1 to 0.4	85°C to 125°C	0.1 to 0.4	0.4 to 0.7
	-	-	130°C to 170°C	-	0.1 to 0.4

Example: a 22212EA bearing, lubricated with standard grease, turning at 1500 rpm in a dusty environment, at 90°C with no other application constraints:

22212 = spherical roller bearing

Thermal reference speed $n_{\theta r} = 5600$ rpm

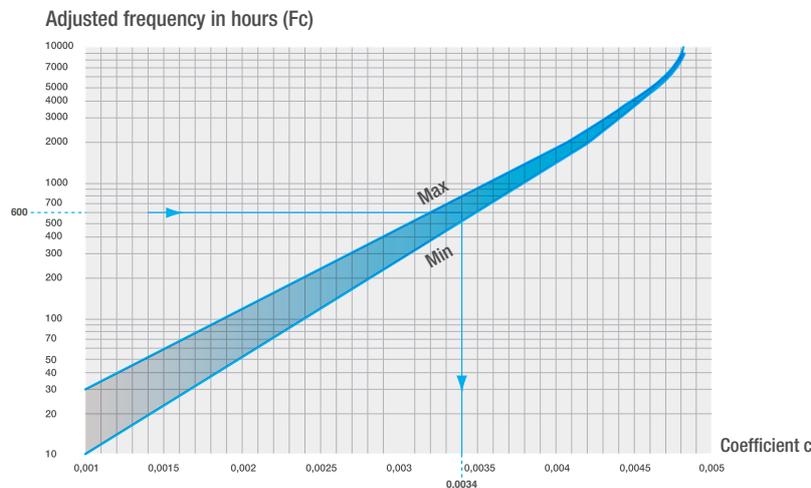

Utilisation speed = 1500 rpm

$$\frac{\text{Utilisation speed} = 1500 \text{ rpm}}{n_{\theta r} \text{ speed} = 5600 \text{ rpm}} = \frac{1500}{5600} = 0.27 \longrightarrow \text{Basic frequency } F_b = 4500 \text{ h}$$

$$\text{Adjusted frequency } F_c = 4500 \times 0.5 \times 0.9 \times 0.3 = 600 \text{ h}$$

$T_e = 0.5 \longrightarrow$ dust
 $T_a = 0.9 \longrightarrow$ normal
 $T_t = 0.3 \longrightarrow$ 90°C

WEIGHT OF GREASE TO BE RENEWED

The adjusted frequency is used to determine the weight of the grease to be used, according to:

- The bearing width B
- Its outer diameter D
- Coefficient c read off the curve by the relation $P = D \times B \times c$ where P = weight of grease (gram)

Example:

for the 22212

(D = 110, B = 28, c = 0.0034)

$P = 110 \times 28 \times 0.0034 = 10$

We shall therefore add approximately

10 g every

600 hours of operation.

In first approximation, we may consider the following values:

FLOW RATE ADJUSTMENT PARAMETERS

Shaft diameter	Manual lubrication frequency (one pump action = 1 cm ³)	Quantity per day	Frequency of replacement of automatic lubricator 120 to 130 cm ³
100 to 120 mm	4 pump actions per day	3 to 4 cm ³	1 month
80 to 100 mm	2 pump actions per day	2 cm ³	2 month
65 to 80 mm	8 to 10 pump actions per week	1.5 cm ³	3 month
50 to 65 mm	8 to 10 pump actions every 15 days	0.7 cm ³	6 month
< 50 mm	8 to 10 pump actions per month	0.3 cm ³	12 month

ADJUSTMENTS

Conditions	Shaft diameter (mm)		ISO tolerance of the shaft	Comments	
	>	≤			
Cylindrical bore bearing (Class 0)					
Rotating inner ring load or indefinite direction load	Light load (1) standard (1) or varying load	18	25	k5	
		25	40	m5	
		40	60	n5	
		60	100	n6	
		100	200	p6	
		200	500	r6	
Static inner ring load	Heavy load or impact load (1)	50	70	n5	Requires a bearing with a radial clearance greater than CN.
		70	140	p6	
		140	200 (2)	r6	
	Inner ring should slide smoothly on shaft	All shaft diameters		g6	For large bearings, tolerance f6 may be applied to ensure that the bearing is capable of moving freely.
Inner ring may not slide smoothly on shaft	All shaft diameters		h6		
Tapered bore bearing (Class 0; complete with an adapter or mounting sleeve)					
All types of load	All shaft diameters		h9/IT5 (3)	h10/IT7 (3) will be sufficient for power transmitting shafts.	

1 Criteria for light, standard and heavy loads.

Light loads:	Dynamic equivalent radial loads $\leq 0.05 C$
Standard loads:	$0.05 C < \text{Dynamic equivalent radial loads} \leq 0.10 C$
Heavy loads:	$0.10 C < \text{Dynamic equivalent radial loads}$

2 If using shaft diameter over 200 mm with impacts or heavy loads, please contact our NTN-SNR experts.

3 "IT5" or "IT7" means that the shaft form tolerance (circularity, cylindricity, etc.) must satisfy tolerance class IT5 or IT7.

Note 1: the table above table applies to solid steel shafts.

Note 2: please use the following formula to calculate the required interference; it determines the value to 1/1000 of the maximum shaft diameter:

If $F' \leq 0.3C_0$	Required interference $\Delta dF(\mu\text{m})$ is $\Delta dF = 0.08 \cdot (d \cdot F' / B)^{1/2}$
If $F' > 0.3C_0$	$\Delta dF = 0.02 \cdot (F' / B)$

(d = Bearing bore (mm) / B = Inner ring width (mm) / F' = Radial load / C_0 = Basic static load)

By taking account of the difference between the ambient temperature and the temperature of an in-service bearing, the appropriate effective interference must be used according to the temperature difference $\Delta T(\mu\text{m})$.

$$\Delta dF = 0.0015 \cdot d \cdot \Delta T$$

(ΔT corresponds to the temperature difference between the bearing in continuous service and the external ambient temperature in °C)

Housing	Conditions		ISO tolerance of the housing	Comments	
	Type of load, etc.	Axial displacement of the outer ring			
Single or two-part housing	Static outer ring load	All types of load	Movable	H7	When a large bearing is used or in case of a significant temperature difference between the outer ring and the housing, tolerance G7 may be applied
		Light load (1) or standard load (1)	Movable	H8	-
		High heat build-up in the shaft and inner ring	Easily movable	G7	When a large bearing is used or in case of a significant temperature difference between the outer ring and the housing, tolerance F7 may be applied
Single housing		Precision rotation must be possible under light to standard load	Generally immovable	K6	-
			Movable	JS6	-
		Very light load	Movable	H6	-
	Indefinite direction load	Light to standard load	Movable	JS7	-
		Standard to heavy load (1)	Generally immovable	K7	-
		High-impact load	Immovable	M7	-
	Rotating outer ring load	Light load	Immovable	M7	-
		Standard to heavy load (1)	Immovable	N7	-
		High impacts or heavy loads on thin-walled housings	Immovable	P7	-

1 Criteria for light, standard and heavy loads

- Light loads: Dynamic equivalent radial loads $\leq 0.05 C$
- Standard loads: $0.05 C < \text{Dynamic equivalent radial loads} \leq 0.10 C$
- High loads: $0.10 C < \text{Dynamic equivalent radial loads}$

Note: the table above applies to steel or cast-iron housings

PRACTICAL INFORMATION

Mounting and removal	42
Fitting & removal tools	48
Services	49

PRACTICAL INFORMATION

MOUNTING AND REMOVAL

Mounting the bearing is an essential stage that determines the service life and proper functioning of the installation. Feedback has shown that incorrect mounting is the cause of 17% of bearing faults remove out in the field.

COLD MOUNTING

Cold mounting is the simplest mode of assembly.

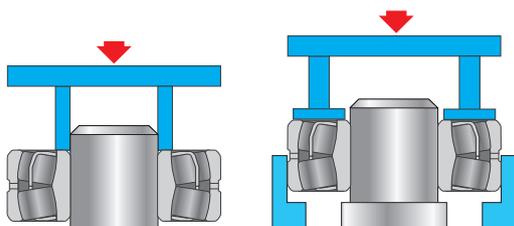

It is particularly suited to small and medium-sized bearings with a moderately tight adjusting.

NTN-SNR RECOMMENDATIONS

Rule 1 the bearing must be firmly fixed to the rotating part

	Analysis of rotation (% Incidence)		Fixing principle
Load fixed in relation to the outer ring (frequency of cases)	Stationary housing and load (95%) Rotating inner ring	Rotating housing and load (0.5%) Stationary inner ring	Inner ring tight on shaft
	Stationary shaft and load (3%) Rotating outer ring	Rotating shaft and load (1.5%) Stationary outer ring	

Rule 2 the sleeve is mounted by applying against the bearing ring with a tight adjusting or simultaneously on both rings. This avoids stressing the rotating body and damaging the bearing.

"For easier mounting and in order to avoid fretting corrosion with the shaft or housing":

- Always use NTN-SNR fitting compound. This thick lubricant preserves the surface quality of parts with mating surfaces. Without this compound, corrosion would progressively cause the adjusting between bearing and shaft (or housing) to deteriorate, ultimately leading to vibrations and ring rotation, causing premature damage to the bearing and the mating surfaces.
- Avoid introducing any pollutant during assembly (metal chips, liquid, etc.)

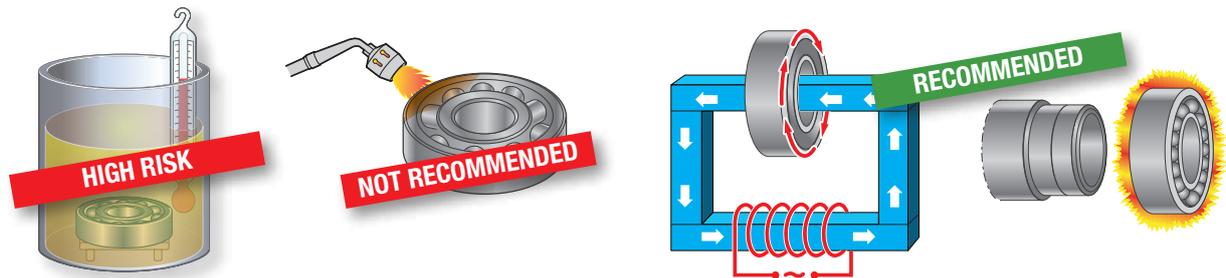

HOT MOUNTING

hot mounting: raising the temperature of the inner ring causes it to expand in order that it can fit effortlessly onto its shaft.

- In the event of tight adjusting on the outer ring, prior to the insertion of the bearing, the housing may be made to expand through heating.
- Conversely, a shaft or a bearing ring can also be frozen using liquefied gas in order to facilitate insertion of the bearing.

NTN-SNR's induction heaters provide the best solution in terms of safety, cleanliness and speed compared with oil-bath heating, hot plates or ovens.

Heating using a blowtorch is to be prohibited. This may generate temperatures locally that alter the hardness of the bearing, and therefore shorten its service life.

Keeping the temperature under control is vitally important for hot-mounting parts correctly.

Therefore, depending on the bearing dimensions, the following temperatures are recommended:

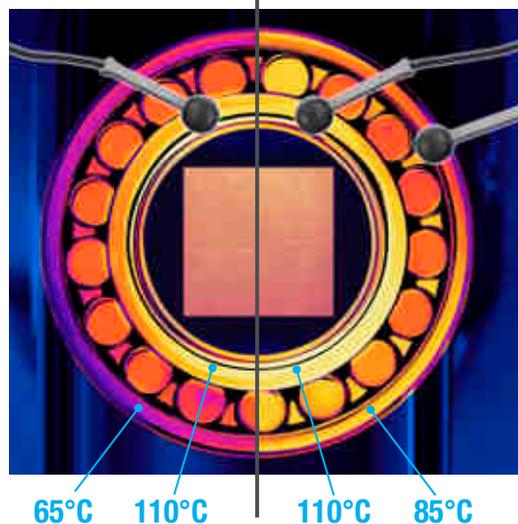

Bore diameter	T° heating temp
Up to 100 mm	+90°C
100 to 150 mm	+120°C
Over 150 mm	+ 130°C

Bearings with seals should not be heated above 80°C.

Heating too fast and too much can alter the properties of the material and significantly reduce the life of the bearing.

However, expanding the inner ring too quickly relative to the outer ring, can subject the rolling housings to significant stresses that can lead to their deterioration or that of the raceway.

ONE SENSOR TWO SENSORS

"A function such as the Temperature mode with 2 probes of SmartTEMP devices makes it possible to control the temperature delta between the rings."

HYDRAULIC MOUNTING

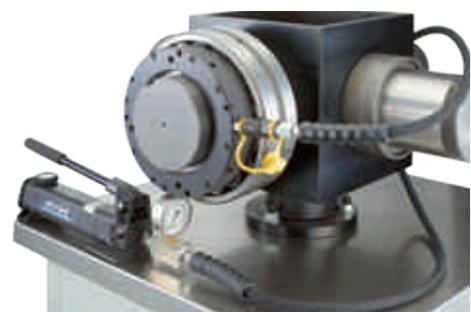

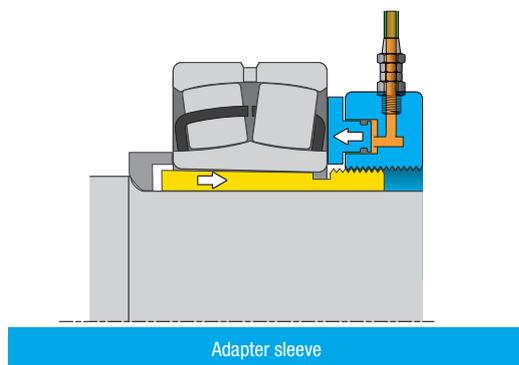

The mounting of large bearings with tapered bores requires considerable effort that is difficult to produce by mechanical screw tightening. The use of hydraulic technology is required in such cases.

Oil is injected under high pressure to create an oil film over the whole of the contact surface between the seat and the inner ring. This reduces the friction generated by the mounting and facilitates tightening of the nut. A hydraulic nut can be used at the same time to develop the necessary mounting force.

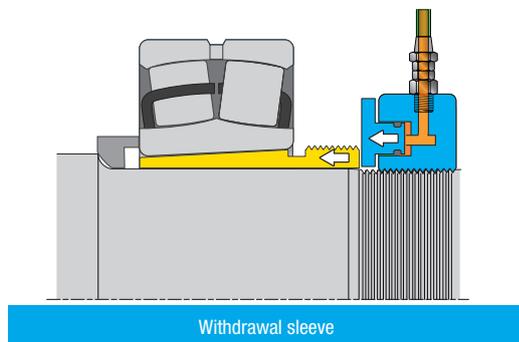

The two principles may also be used simultaneously to make mounting easier. The residual clearance is checked using feeler gauges or a comparator which measures the sink depth on the tapered seat.

TWO TYPES OF MOUNTING ARE SUITED TO THIS METHOD:

Cylindrical shaft associated with an adapter sleeve

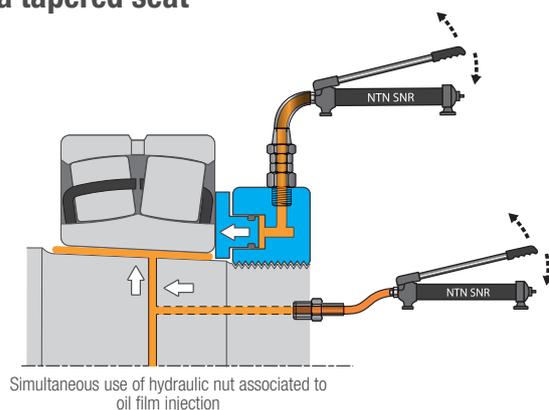

Mounting on adapter sleeve with a hydraulic nut

Mounting on withdrawal sleeve by indirect pushing of the hydraulic nut

Note: You could use the same hydraulic nut for assembly and disassembly.

On a tapered seat

"For bore diameters above 60 mm, a hydraulic solution must be used."

CHECKING THE INTERNAL RADIAL CLEARANCE ON ASSEMBLY

AXIAL CLEARANCE

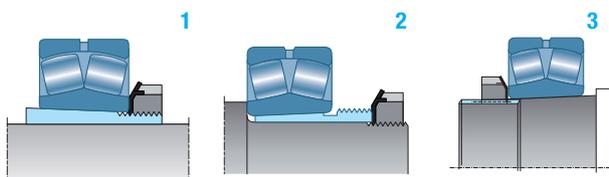

Since the axial clearance J_a is a function of the radial clearance J_r , it can be calculated by means of the following approximation formula:

$$J_a = 2.27 Y_0 \cdot J_r$$

WHY IS IT IMPORTANT TO MEASURE THE RADIAL CLEARANCE?

Spherical roller bearings with two rows of tapered bore can be mounted in various ways:

- By using an adapter sleeve (1)
- A withdrawal sleeve (2)
- Or directly on the tapered shaft seat (3)

Locking the nut allows the bearing to be tightened. This causes the inner ring to expand and reduces the internal clearance. To prevent the bearing from locking due to too great a reduction in clearance, it is necessary to check the degree of tightness of the nut. The tightness is checked by measuring the bearing clearance before and after mounting.

Prior to measurement of clearance

Locate the radial clearance before mounting (catalogue data) shown in the table on the following page (see blue area).

Bearing clearance is measured with feeler gauges.

Place the bearing in a vertical position, facing, with the rollers in line with the bearing.

Turn the bearing manually in order to put the rollers in place.

Radial clearance measurement

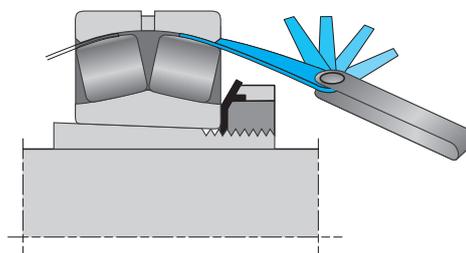

The bearing must be held still during this measurement.

The feeler gauges are used as follows.

Slide them at an angle between the outer ring raceway and the rollers without load, without rotating the bearing.

Start with the mini gauge and insert gauges of increasing thickness until the value of the radial clearance is reached.

The actual radial clearance value is located between the gauge that passes and the one that fails to pass.

How to measure the clearance after mounting?

There are two ways to check that the clearance has been correctly reduced after mounting:

- **Using feeler gauges:** proceed in the same way as above (see green area in the table on the following page)
- **By axial displacement:** using a comparator and a hydraulic pump, position the bearing within the range of corresponding values indicated by the rest blade (see grey area in the table on the following page)

During tightening, monitor the reduction of clearance so that the prescribed limit is not exceeded.

SPECIAL CASE: SEALED BEARINGS

Only the axial displacement can be checked to obtain the right radial clearance that also corresponds to a rotation in °.

The last column of the table contains our recommendations for the rotation of the nut in order to obtain the right axial displacement for your sealed bearing.

SPECIAL CASE: OVERSIZE BEARINGS

For large bearings, do not use feeler gauges larger than 15/100th of a mm, which are too rigid to fit the curve of the bearing raceway and prefer using a combination of thinner distance pieces.

If using an EE sealed spherical roller bearing, a feeler gauge cannot be used.

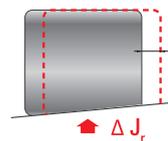

Bearing nominal bore (mm)		Before assembly According to ISO 5753 (mm)						After assembly Feeler gauge*						Axial displacement (mm)				Recommended rotation for the locking nut

*Practical measurement of clearance per 1/100 mm using feeler gauges. The values less than 4/100 mm, use laminated shims.

Relation between the axial displacement (a) of a bearing with tapered bore and the corresponding reduction of its clearance J_r :

Taper 1/12 $a = 12 \Delta J_r / t_i$

Taper 1/30 $a = 30 \Delta J_r / t_i$

a = axial displacement
 J_r = radial clearance reduction

t_i = clearance reduction rate on inner ring: $t_i = 0.75$ if the bearing is directly mounted on a solid shaft tapered seat.
 $t_i = 0.7$ if the bearing is mounted on a tapered sleeve.

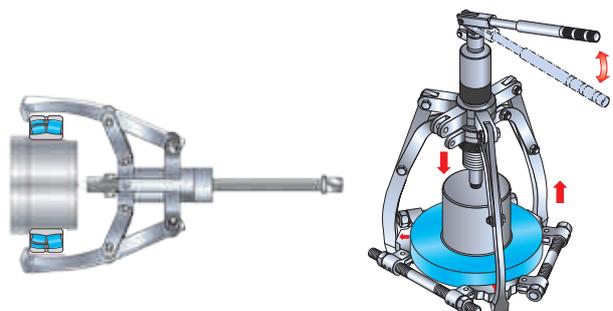

MECHANICAL DISMOUNTING

Dismount cleanly: look after your equipment and save time, safely.

Wherever possible, the bearing should be extracted by exerting force on the tightened ring. There are numerous types of extractor, depending on the grip offered by the bearing, its accessibility and the extraction force required.

Extractors equipped with a pump and hydraulic cylinder allow the operator to develop very high extraction efforts, using their own muscular strength. They are easy to use, due to the fact that their arms are self-centring.

To remove a damaged or oscillating bearing, slide a ring separator between the puller and bearing if possible.

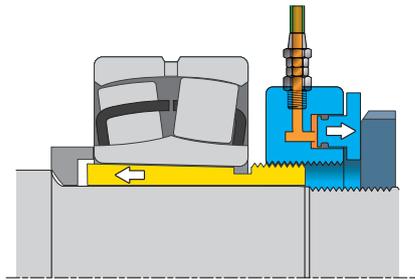

HYDRAULIC DISMOUNTING

bearing seats are equipped with distribution channels and grooves for removal by means of hydraulic pressurisation. Likewise, the NTN-SNR adapter and withdrawal sleeves are equipped with these devices for shafts of 200 mm and above.

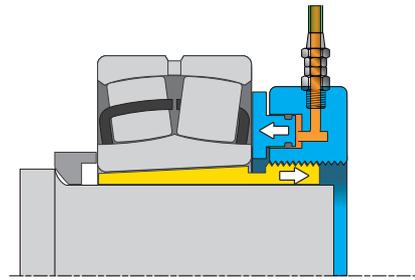

This method is quick and reliable: it requires a high pressure pump with a maximum power rating in the case of tapered seats. In the case of a cylindrical seat, it is necessary to maintain high pressure and accompany this with the removal of the bearing using mechanical extraction methods.

If an adapter or withdrawal sleeve was used during mounting, a hydraulic nut can be used for quick and effortless dismounting.

HYDRAULIC DISMOUNTING ON ADAPTER / WITHDRAWAL SLEEVE

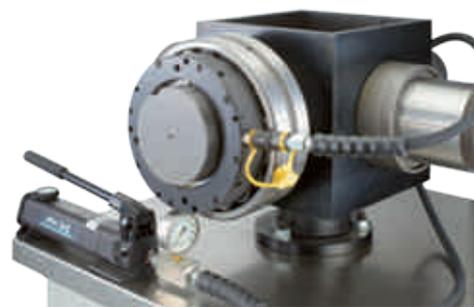

Screw the hydraulic nut on the adapter sleeve without pressing against the bearing.
Inject oil extraction up the sleeve.

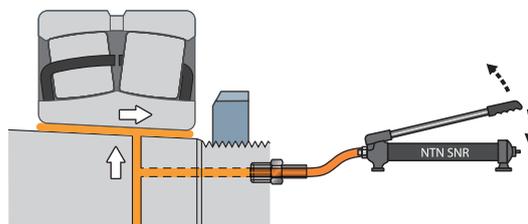

Screw the hydraulic nut on the sleeve removal, the piston in contact with the bearing.
Inject oil extraction up the sleeve.

Extraction of the adapter sleeve with a hydraulic nut

Extraction of the withdrawal sleeve with a hydraulic nut

Principle of removing hydraulic oil injection channels

Hydraulic dismounting

FITTING & REMOVAL TOOLS

SmartTEMP

THE ONLY TOOL FOR THE SAFE, CONTROLLED HEATING OF BEARINGS, PINIONS, COLLAR RINGS, ETC.

Drawing strength from a 30-year track record in the professional induction heating market, NTN-SNR is now able to present its innovative new range of induction heaters. These new-generation heaters effectively address all your needs, from heating workpieces through to more sensitive parts that require cutting-edge technology for safe heating. Heaters are easy and safe to use with their touchscreen. The interface menu is displayed in the operator's language to maximise efficiency, the likes of which have never been seen before in the market.

ELIMINATE ALL RISKS WHEN MOUNTING BEARINGS

17%

of premature bearing failures are caused by poor mounting

CORRECT BEARING MOUNTING

is essential for increasing the service life

HOT MOUNTING METHOD

with the induction heater reduces any damage during assembly

COLD MOUNTING

Tool case for quick, accurate bearing fitting in complete safety.

DISMOUNTING TOOLS

Hydraulic or mechanical dismounting: All kinds of pullers (2 or 3 arms) for a safe and clean operation whatever the position and the size of the bearing.

HYDRAULIC MOUNTING

Precise, effortless with a revolutionary nut, always ready for use thanks to its "back & forth" feature!

SERVICES

Experts
& Tools

EXPERTS & TOOLS: THE NTN-SNR TEAM OF EXPERTS CAN SUPPORT YOUR ORGANISATION TO OBTAIN THE BEST PERFORMANCE FROM YOUR BEARINGS AND YOUR OPERATIONS

TRAINING

Improve the skills of your maintenance technicians and designers in bearing selection and maintenance. Whether at our training school or on your premises with our BEBOX van, we can provide made-to-measure training courses covering both theory and practice, because all customers are different.

DAMAGED BEARING DIAGNOSIS

Let our experts determine the causes of your bearing failures in our lab or on your site. Their reactivity and advice can provide the keys to your improvements.

TECHNICAL ASSISTANCE FOR BEARINGS AND LUBRICATION SYSTEMS

Rely on our experts to supervise your maintenance operations: bearing dismounting and fitting, lubrication system set-up and improvement, vibration analysis and so on.

MAINTENANCE AUDIT

Benefit from a unique appraisal of your maintenance organisation, performed by our plant maintenance managers. Gain productivity thanks to a pragmatic action plan resulting from a peer-to-peer approach.

TOOL HIRE

Experts & Tools offers a wide range of large bearing maintenance tools for rent, whether induction heaters, hydraulic nuts or pumps.

Bearings available with cylindrical and tapered bores Bearings with tapered bores are generally fitted with adapter or withdrawal sleeves. All types of clearances are available from stock or on request. Special clearances and special precisions are available on request.

Bearings available with cylindrical and tapered bores. Bearings with tapered bores are generally fitted with adapter or withdrawal sleeves. All types of clearances are available from stock or on request. Special clearances and special precisions are available on request.

ASSOCIATED PLUMMER BLOCKS

SNCD OVERSIZE SPLIT PLUMMER BLOCK

In accordance with ISO 113:2010 for mounting spherical roller bearings with a cylindrical and tapered bore.

- Plummer block material: spheroidal graphite iron
- Compatible with temperatures down to -40°C
- Excellent heat dissipation with its extra-wide contact support surface
- Increased dimensional stability with a reinforced X-shaped sub-structure and wide circular rib around the bearing
- Less maintenance required and longer bearing service life
- For mounting spherical roller bearings in the 222XX, 223XX, 230XX and 231XX series
- Sealing systems: labyrinth and taconite seals for extreme conditions
- Different connection options available for lubrication or control systems
- For shaft diameters from 115 mm to 500 mm

SNG500 / SNCD500 SPLIT PLUMMER BLOCK

In accordance with ISO 113:2010 for mounting spherical roller bearings with a cylindrical and tapered bore.

- Plummer block material: lamellar graphite cast iron and/or spheroidal graphite iron (SNCD)
- Increased stability and dimensional rigidity with all types of load
- Excellent heat dissipation
- Fewer constraints in the bearing
- Less maintenance required and longer bearing service life
- Sealing systems: five types of seals available for all types of application
- Fast implementation and easy maintenance thanks to the enhanced design
- For shaft diameters from 20 mm to 140 mm

SPW/SFCW – ONE-PIECE PLUMMER BLOCK FOR HEAVY LOADS

- Suited to highly demanding, heavy industrial environments
- Components treated for corrosion protection
- Enables rapid replacement of patented inserts
- Equipped with sealed spherical roller bearings
- Reduced maintenance time and increased productivity
- SPW range interchangeable with SN bearing housing units
- Shaft diameter: 50 mm – 140 mm

FLANGED ONE-PIECE PLUMMER BLOCK 722500 WITH GREASE LUBRICATION

Flanged one-piece plummer block for positioning a cylindrical or tapered spherical roller bearing mounted on an adapter sleeve

- Compact and robust bearing unit design
- Housing material: lamellar graphite cast iron
- Suitable for bearings in the following series: 12..K, 22..K, 222..K
- Version available with a plug (type A) or through-shaft (type B)
- Flange design with 3 or 4 mounting holes
- Integrity using a felt strip seal
- For shaft diameters from 20 mm to 100 mm
- Relubrication possible

SNOE OIL-LUBRICATED SPLIT PLUMMER BLOCK-UNIT

- Suited to spherical roller bearings
- Perfectly suited to operating conditions with heavy loads and high rotation speeds
- Material: EN-GJS-600-3 for high rigidity
- Internal distribution of oil via a lubrication ring
- Seal by means of a labyrinth seal system
- Fitted with an oil level indicator
- Possible integration in an oil circulation system (with or without heating)
- Excellent heat dissipation
- Standard applications: industrial fans, hammer crushers, extraction, steelworks, chemical and petrochemical industries, power plants, ventilation mechanisms, drying systems, incinerators and air-conditioning systems
- Maximum shaft dimensions: 260 mm (the largest oil-lubricated plummer blocks available as standard on the market)

SNOE OIL-LUBRICATED SPLIT PLUMMER BLOCK-UNIT (COMPACT VERSION)

- Suited to spherical roller bearings
- Seal by means of a labyrinth seal system
- Can replace a grease-lubricated split plummer block-unit when the rotation speeds are too high or when the operating temperatures risk damaging the bearing
- Interchangeable with the same-size SN bearing housings
- Fitted with an oil level indicator
- Shaft diameter: 60 mm – 140 mm

LUBRICATION PRODUCTS

We can provide support for lubrication projects from design to installation, offering lubricants specially selected for specific applications, together with single-point or multi-point lubrication systems according to each process size and requirements.

TYPES OF GREASE AND OIL

Designed for the demands of each application to ensure that bearings operate at their best.

Chain Oil

AUTOMATIC SINGLE-POINT LUBRICATION SYSTEMS

Automatic single-point lubrication systems ensure constant and regular lubrication of the bearings.

They can easily be incorporated into different types of application (mechanical and motor industries, steelworks, paper mills, etc.) and they provide improved lubrication systems without involving any changes in installations.

MULTI-POINT LUBRICATION: POLIPUMP

A POLIPUMP is the lubrication system that is best suited to lubricate several points. Available in versions with 12, 24 or 35 outlets, providing independent output rates of between 0.01 cc and 0.13 cc per cycle for each point, at a maximum pressure level of 80 bar, and featuring a large grease tank, a POLIPUMP constitutes a very widespread lubrication system that is very easy to use.

"Our lubrication recommendations: it is vital that satisfactory lubrication is obtained as soon as the bearings start to rotate. In the case of lubrication using grease, the grease needs to occupy the entire available volume and, in particular, the space between the cage and the inner ring."
